## HUMIDITY INDICATORS

This invention relates to silica-based humidity indicators.

Cobalt chloride indicator gels are used in a range of applications, e.g. to indicate moisture change in gas drying columns. Other drying applications include their use in transformer  
5 breathers, tank breathers, in the protection of electronics and telecommunication systems and in laboratory desiccators. It is estimated that approximately 2000 tonnes of cobalt chloride indicator gel are used annually on a global basis.

Cobalt-containing gels for use as humidity indicators have been disclosed in US-A-2460071 (disclosing cobalt chloride), US-A-2460069 (disclosing cobalt bromide),  
10 US-A-2460073 (disclosing cobalt iodide), US-A-2460074 (disclosing cobalt thiocyanate), US-A-2460065 (disclosing cobalt sulphate) and US-A-2460070 (disclosing cobalt phosphate).

Indicator silica gel is currently produced by impregnating humidified silica gel or a silica hydrogel with a cobalt chloride solution to produce a dry granular end-product which contains a minimum of 0.5% cobalt chloride and which is blue in colour, changing to pink when water has  
15 been adsorbed. Humidified gel is silica gel that has been saturated with water from the vapour phase in order to avoid decrepitation upon impregnation. If the cobalt chloride solution is added directly to the dried gel, the grain size is reduced.

Cobalt chloride has recently been classified as a Category 2 carcinogen (notification from the EEC, 15/12/98) with the consequence that the use of cobalt chloride indicator gel in industrial  
20 applications will require much tighter control to ensure exposure limits are strictly controlled. If acceptable alternatives to the cobalt chloride indicator gel were not available to indicate when saturation had occurred in gas/air drying applications, for instance, this could have serious implications on the users' downstream processes, e.g. corrosion through moisture damage.

US-A-2460072 and US-A-2460067 also disclose copper(II) chloride and copper(II) bromide, respectively, but these compounds are not considered suitable candidates for a  
25 commercial silica gel-based humidity indicator because of potential toxicity and environmental considerations.

It has been demonstrated that the vanadium compound  $\text{VOCl}_3$ , when impregnated into silica gel gives a colour change from colourless to yellow to orange to red to brown as humidity  
30 increases - see the following references:

Belotserkovskaya et al., "Indicator properties of vanadium-modified silicas and zeolites" *Zh. Prikl. Khim. (Leningrad)*, **63**(8), 1674-9;

Malygin, A.A. "Synthesis and study of physicochemical properties of vanadium-containing silica - a humidity indicator", *Sb. Nauch. Tr. VNII Lyuminoforov I Osobo Chist. Veshchestv*, **23**, 24-8; and

35 Malygin, A.A. et al, "Study of properties of vanadium-containing silica gel", *Zh. Prikl. Khim. (Leningrad)*, **52**(9), 2094-6.

However,  $\text{VOCl}_3$  is corrosive, toxic and difficult to prepare and handle.

The present invention therefore addresses the problem of producing an alternative, safe indicator gel to those which are cobalt-based or contain a transition metal salt which is considered to be toxic.

According to one aspect of the present invention there is provided a humidity indicator  
5 compound comprising a silica-based carrier containing an iron(II) and/or iron(III) salt or salts as the active indicator.

A second aspect of the present invention resides in the use, as a humidity indicator, of a compound comprising a silica-based carrier containing an iron(II) and/or iron(III) salt or salts as the active indicator.

10 According to a third aspect of the present invention there is provided a method of monitoring the humidity level within an atmosphere comprising exposing a dried silica-based carrier containing an iron(II) and/or iron(III) salt or salts to said atmosphere and observing colour changes therein.

Typically, humidified silica gel is used as the carrier; however other forms of silica may  
15 be used in the production of the silica-based carrier, e.g. silica hydrogel or dry silica gel. The silica-based material may have any of the physical forms normally available. In particular, the form can be irregular granules or approximately spherical beads (often called spherical or beaded silica gel).

The presence of the iron salt imparts a yellow or amber colour to the dry silica-based  
20 carrier. When the indicator is exposed to moisture, it then adsorbs water and the colour is observed to fade until it becomes almost colourless when the silica-based carrier is almost saturated with water. This effect has been observed to be a general effect for those iron salts which have been examined.

Once the extent of exposure of the indicator to moisture has resulted in a change of  
25 colour from yellow/amber to almost colourless the silica-based carrier may be processed, e.g. by heating, to restore its colour, and re-used for humidity monitoring.

The effect referred to above, i.e. colour change from yellow or amber to almost colourless, has been observed in all iron salts examined, e.g. simple iron salts such as ferric sulphate, ferric chloride or ferric nitrate and salts having at least two cations of which one is  
30 iron(II) or iron(III), examples of which are ammonium iron(III) sulphate, ammonium iron(II) sulphate and potassium iron(III) sulphate. The effect has been found to be particularly pronounced for the double sulphates or alums.

While not wishing to be bound by theory, the effect is thought to be related to hydrolysis and formation of coloured, polymeric Fe-hydroxy species. In dry silica, such species are thought  
35 to be polymerised, and also bound to the silica, to a greater extent than in humidified gel. The higher the degree of polymerisation, and possibly also bonding to the silica, the more intense the colour.

The effect would appear to be related to pH. Those iron salts which exhibit higher pH values when dissolved in water give more intense colours, and more pronounced colour changes, than those which exhibit lower (i.e. more acidic) pH values, possibly due to a higher degree of polymerisation of the Fe-hydroxy complexes. Thus ammonium iron(III) sulphate at 10% by weight in water has a pH of 1.7 and produces a silica-based carrier with a deep amber colour, whereas a 10% solution of ferric chloride has a pH of 1.3 and results in a paler yellow shade. The colour of the simple salts can be enhanced by adjusting the pH to higher values, comparable to the alums. This may be achieved by the addition of small amounts of sodium hydroxide solution.

Normally an iron(III) salt is employed; however, ferrous counterparts of the ferric salts may also be used since the ferrous ion readily oxidises to the ferric state.

Typically, the silica gel used has a BET surface area in the range of 200 to 1500 m<sup>2</sup>/g. The pore volume of silica gel may be in the range of 0.2 to 2.0 ml/g, as measured by nitrogen absorption. For example, Sorbsil desiccant gel (Sorbsil is a Trade Mark of Crosfield Limited) typically has a surface area of about 800 m<sup>2</sup>/g and a pore volume of about 0.4 ml/g. Surface area is determined using standard nitrogen adsorption methods of Brunauer, Emmett and Teller (BET).

The amount of iron present in the silica-based carrier is preferably at least about 0.01 per cent by weight of iron, determined as Fe, relative to the dry weight of the carrier, typically up to about 2.0 per cent and usually in the range of about 0.01 per cent to about 1.0 per cent by weight of the dry weight of the silica-based carrier. The dry weight of a prepared humidity indicator, based on silica gel, according to the invention can be determined by placing a weighed sample (approx. 20 grams) in an oven at 145° C for 16 hours and then weighing the dried material.

According to another aspect of the present invention there is provided a method of producing a humidity indicator comprising soaking silica-based carrier with a solution of an iron(II) and/or iron(III) salt to secure impregnation of the carrier and drying the impregnated carrier.

Typically the indicator gel is prepared by contacting the silica-based carrier with a solution of iron salt containing 1 per cent by weight or higher (up to the saturation point) of the iron salt, e.g. by soaking humidified white silica gel in the iron salt solution. Humidified gel is preferred, but the use of dry gel is acceptable. When dry gel is used, the granules decrepitate, so that the product has a smaller particle size than the original product, but, generally, the particle size is still satisfactory for use as a drying agent. In the case of ammonium iron(III) sulphate (herein referred to as iron(III) alum), the solution may range from 1 per cent to approximately 50 per cent by weight (saturation at 25° C), or higher at higher temperatures. Preferably, the solution contains 10 to 40 per cent by weight iron(III) alum at 25° C. The use of a high concentration of iron salt helps to reduce the processing time for preparing the indicating silica-based product. The gel is typically soaked in the solution for a period of from 10 minutes to 10 days, preferably 1 to 30 hours, more preferably 2 to 24 hours. The excess solution is drained and the gel dried at 105 to 230° C whereupon it develops its amber colour. An impregnated product dried in this

manner will usually have a weight loss after heating at 145° C for 16 hours of less than 10 per cent by weight. Preferably, the weight loss at 145° C is less than 2 per cent by weight.

The invention is illustrated by the following, non-limiting examples.

5

#### EXAMPLE 1

Sorbsil silica gel (commercially available from Crosfield Limited of Warrington, England) was exposed to humidity or steam until the pore system was totally saturated with water transported from the vapour phase. 50 g of this humidified gel was impregnated with a ferric salt by soaking the gel in 200 ml of 20 per cent by weight iron(III) alum solution for 24 hours. The gel was drained and then dried at 145° C for 16 hours. 6 g samples of the impregnated, dried gel were placed in a series of glass tubes and air at various levels of relative humidity (RH) passed through the gel for 7 hours at a flow rate of 4 litres/minute. After exposure to moisture-containing air for this length of time, the colour of the gel samples was measured using a Minolta CR200 Chromameter, calibrated to a standard white plate and using CIE Illuminant C and a 2° observer angle. The results, expressed according to the L\*, a\*, b\* system, are given in Table 1 below.

10

15

TABLE 1

% RH	% weight gain	L*	a*	b*
0	0.0	39.96	10.96	32.38
20	8.4	44.40	8.95	35.47
40	14.9	48.13	4.39	23.53
50	18.2	50.00	1.67	15.90
80	25.6	59.94	-0.30	12.30

20

The increase in lightness (L\*) and decrease in redness (a\*) and yellowness (b\*) is apparent from the above data and is readily observed visually, allowing an obvious indication of when the gel has become saturated with moisture. Visually, the gel appears almost colourless after exposure to 50% RH air at 4 litres/min for 7 hours.

25

#### EXAMPLE 2

A further batch of silica gel was prepared according to the method of Example 1 and the gel was soaked in the ferric alum solution for 4 hours, rather than 24 hours. The product was similarly exposed to moist air and the results are given in Table 2 below.

30

TABLE 2

% RH	Colour	% weight gain	L*	a*	b*
0	Deep amber	0.0	40.77	+13.23	35.13
20	Pale amber	11.7	45.62	+6.94	36.90
40	Yellow	20.6	56.48	+0.59	23.94
50	Pale Yellow	25.4	53.64	-0.28	17.90
80	Almost colourless	31.0	57.93	-1.74	14.28

5 This product shows an improvement over Example 1 especially in terms of water adsorption capacity.

**EXAMPLE 3**

10 Samples of ferric salts were placed in the oven at 145° C for 16 hours to observe the effect of dehydration and to see if any colour changes observed matched those obtained with silica-based carriers impregnated with the ferric salts. Observations are given below in Table 3.

TABLE 3

Salt	Colour prior to drying	Colour after drying
Ferric alum	pale lilac	light buff
Ferric sulphate	light buff	light buff
Ferric chloride	deep yellow	dark brown (decomposed to ferric oxide)
Ferric nitrate	pale violet	dark brown (decomposed to ferric oxide)

15 Where colour changes were observed, it was found that they did not correspond to those seen in the impregnated carrier. This indicates that the colour change observed in the carrier impregnated with iron(III) salts is not due to a simple hydration/rehydration effect as with cobalt and copper salts.

**EXAMPLE 4**

20 Silica gel was impregnated with various iron salts using a similar method to that described in Example 1. The details of the reaction conditions are given in Table 4 below. In these laboratory experiments particular care was taken to remove as much excess solution as possible from the gel using tissue before the oven drying. During oven drying the treated

materials were spread in as thin a layer as possible. This was found to give a product with a more homogenous colour.

TABLE 4

Sample	Iron salt	Solution strength	Ratio gel/solution	Soaking time
A	Potassium iron alum	10 %	50 g/200 ml	24 hours
B	Ferric sulphate	40 %	50 g/200 ml	24 hours
C	Ferric chloride	10 %	100 g/200 ml	2.5 hours
D	Ferric nitrate	10 %	100 g/200 ml	2.5 hours

5

The samples were exposed to moist air as described in Example 1 and the results are given in Table 5 below.

TABLE 5

10

Sample	% RH	% moisture	Colour	L*	a*	b*
A	0	0	Amber	50.97	+7.54	+35.06
	20	10.5	Amber	49.55	+6.61	+34.73
	40	20.9	Yellow	54.34	+2.00	+25.10
	50	23.6	Almost colourless	59.63	-0.23	+17.80
	80	26.1	Almost colourless	60.20	+0.29	+18.02
B	0	0	Yellow/amber	41.94	+4.15	+29.37
	20	11.0	Yellow	53.22	+2.55	+30.21
	40	19.4	Yellow	53.75	+1.32	+27.22
	50	21.5	Pale yellow	57.67	+1.14	+26.74
	80	23.8	Almost colourless	55.01	-0.32	+22.54
C	0	0	Amber	39.02	+10.12	+32.63
	20	11.2	Yellow/amber	48.05	+4.20	+28.30
	40	23.5	Pale yellow/amber	52.35	+2.88	+25.76
	50	27.1	Pale yellow/amber	54.62	+1.79	+23.67
	80	31.5	Pale yellow/amber	55.45	+1.46	+23.29
D	0	0	Amber	44.49	+7.17	+31.10
	20	10.8	Pale amber	45.79	+6.47	+29.90
	40	23.2	Pale amber	53.71	+4.14	+28.64
	50	26.6	Pale amber	51.47	+3.62	+26.16
	80	29.6	Pale yellow	53.74	+2.68	+25.34

The chloride and nitrate show a less marked colour change than when alum is used. Nevertheless some lightening of colour is visible to the human eye and the trend can still be detected using the L\*a\*b\* system.

## 5 EXAMPLE 5

50 g of humidified gel, prepared as in Example 1, was soaked in 200 ml of a 20 per cent by weight solution of ammonium iron(II) sulphate for 4 hours and dried as in Example 1. The product was exposed to moist air as in Example 1 and the observed colour changes are shown in Table 6 below.

TABLE 6

% RH	% water absorbed	Colour	L*	a*	b*
0	0	Amber	44.09	+15.81	+43.11
20	11.4	Amber	44.97	+14.44	+40.84
40	23.4	Pale amber	52.82	+8.43	+36.41
50	26.6	Pale yellow/amber	52.05	+6.08	+32.99
80	30.0	Pale yellow	57.91	+2.62	+27.56

15

Ammonium iron(II) sulphate has the normal green colour of ferrous salts. However, silica gel impregnated with it and dried has the amber colour associated with iron(III) salts.

## EXAMPLE 6

20

Samples of commercially available beaded silica gel from three suppliers were humidified and then impregnated with 20 % iron(III) alum solution for 7 hours, dried at 145° C overnight and the colour recorded. Samples were then placed in a desiccator at 100 % relative humidity for a week and the colour recorded.

25

The desiccant silica gel beads used in this experiment, and their suppliers, were:

Bead type/size	Supplier
"TS6", 2-5 mm	QingDao HaiYang Chemical Group Co. Ltd., 7 Mian Yang Road, QingDao, China.
2-5 mm	Silgel Packaging Ltd., 2 Horton Court, Hortonwood 50, Telford, Shropshire, UK.
Ca. 1-3 mm	Engelhard Corp., 600 E. McDowell Road, Jackson, MS 39204, U.S.A.

Colour changes for the desiccant beaded silica gel impregnated with iron(III) alum are given in Table 7 below.

TABLE 7

Supplier		Colour	L*	a*	b*
Haiyang	before exposure	Amber	46.05	+10.10	+37.91
	after exposure	Almost colourless	53.10	-1.58	+18.05
Silgel	before exposure	Amber	48.69	+13.64	+43.57
	after exposure	Almost colourless	61.07	-2.16	+16.04
Engelhard	before exposure	Amber	50.27	+16.18	+51.36
	after exposure	Almost colourless	58.03	-1.35	+15.50

In each case the beaded silica gel shows a pronounced colour change from amber when dry to almost colourless when humidified. This is the same behaviour as is observed when an irregular granular silica gel is used.

#### EXAMPLE 7

Dry silica gel, when placed in water (or an aqueous solution), is known to decrepitate. However, decrepitation is not necessarily a problem in the preparation of acceptable indicating silica gel. To demonstrate this, 50 g dry silica gel having a size range of approximately 2.5 to 6.0 mm was soaked in 200 ml of 20 per cent by weight iron(III) alum solution for 4 hours and then dried at 145° C overnight. The colour of the resulting gel was measured before and after being left in a desiccator at 100 % relative humidity for 3 weeks. The colour changes are shown in Table 8 below. A sieve analysis was carried out before and after the impregnation step to demonstrate the effect of decrepitation on particle size distribution. The results are shown in Table 9 below.

TABLE 8

	Colour	L*	a*	b*
before exposure	Amber	58.32	+9.97	+53.29
after exposure	Pale yellow	66.67	-2.84	+20.06

TABLE 9

Particle size (mm)	Weight % before impregnation	Weight % after impregnation
> 5.6	4.74	0.00
3.55 – 5.6	63.31	0.71
1.6 – 3.55	31.91	36.17
1.0 – 1.6	0.04	36.35
0.5 – 1.0	0.01	22.40
< 0.5	0.00	4.37

There had been some breakdown in particle size as a result of the decrepitation but this does not interfere with the humidity indication. The gel in this example still showed the expected amber to nearly colourless colour change and the particle size distribution was still acceptable for normal desiccant use.

**EXAMPLE 8**

100 kg of humidified 2.5 – 6.0 mm silica gel prepared as in Example 1 was soaked in 180 litres of 20 per cent by weight iron(III) alum solution for 4 hours. A pump was used to keep the solution circulating at a rate of between 25 and 50 litres per minute. The gel was then withdrawn, allowed to drain and then dried at 150° C overnight in 2 cm deep trays in an oven. Colour and adsorption capacity were measured for the fresh material as in Example 1. Analysis showed it to contain 0.34 % Fe.

200 g of orange indicator gel, made as described above, were placed in a bowl in a desiccator containing water. The relative humidity in this desiccator was nearly 100 % at 25° C. After about two weeks exposure to this high humidity the gel had decolourised. It was then oven dried at 145° C overnight and the process repeated. This exposure and regeneration was carried out ten times. After the ten cycles of humidifying and drying the colour and adsorption capacity of the gel were measured again as in Example 1 and compared to the original material. The results are shown below in Tables 10 and 11.

**TABLE 10**  
**Effect on colour.**

Sample		L*	a*	b*
Fresh	before exposure	42.80	+11.28	+37.71
	after exposure	61.92	-1.02	+15.18
After 10 cycles	before exposure	41.74	+11.48	+37.86
	after exposure	56.72	-1.64	+12.58

**TABLE 11**  
**Effect on adsorption capacity.**

Sample	% RH	% water adsorbed
Fresh	20	11.6
	40	22.9
	50	28.0
	80	31.2
After 10 cycles	20	10.1
	40	22.5
	50	27.6
	80	30.8

Visually, the fresh and regenerated gels were indistinguishable. There had been no  
5 deterioration in colour shade, intensity or distribution and the colour change effect was also  
unaffected. In addition, the adsorption capacities show no adverse change after ten regeneration  
cycles.

Similar recycle results can be obtained with other iron salts but it has been found that the  
drying temperature may need to be kept below about 100° C when certain salts (e.g. FeCl<sub>3</sub>) are  
10 used, in order to avoid the development of an uneven colouration.

**CLAIMS**

1. A humidity indicator compound comprising a silica-based carrier containing an iron(II) and/or iron (III)salt or salts as the active indicator.
2. The use, as a humidity indicator, of a compound comprising a silica-based carrier containing an iron(II) and/or iron(III) salt or salts as the active indicator.
3. A method of monitoring the humidity level within an atmosphere comprising exposing a dried silica-based carrier containing an iron(II) and/or iron(III) salt or salts to said atmosphere and observing colour changes therein.
4. An indicator as claimed in any one of Claims 1 to 3 in which the salt is a simple iron salt.
5. An indicator as claimed in any one of Claims 1 to 3 in which the salt is a salt containing more than one cation of which one is iron(II) or iron(III).
6. An indicator as claimed in Claim 4 or 5 in which the salt is selected from one or more of ferric sulphate, ferric chloride and ferric nitrate, ammonium iron(III) sulphate, ammonium iron(II) sulphate and potassium iron(III) sulphate.
7. An indicator as claimed in any one of the preceding claims in which the iron(II) or iron(III) salt is present in an amount in the range 0.01 per cent to 2.0 per cent by weight expressed as Fe based upon weight of dry carrier.
8. A method of producing a humidity indicator comprising soaking silica-based carrier with a solution of an iron(II) and/or iron(III) salt or salts to secure impregnation of the carrier and drying the impregnated carrier.
9. A humidity indicator in the form of an iron impregnated silica-based carrier produced by the method as claimed in Claim 8.
10. A humidity indicator as claimed in any one of the preceding claims in which the carrier comprises silica gel.
11. A humidity indicator as claimed in claim 10 in which the silica gel is humidified silica gel.

12. A humidity indicator as claimed in claim 10 or 11 in which the silica gel is beaded or granular silica gel.

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	DATABASE WPI Section Ch, Week 198345 Derwent Publications Ltd., London, GB; Class J04, AN 1983-813626 XP002142696 & SU 989 479 A (LENINGRAD ZHDANOV UNIV), 15 January 1983 (1983-01-15)	1-4, 6, 7, 10
A	abstract	8, 9, 11, 12
X	DE 19 52 539 A (SIEMENS AG) 22 April 1971 (1971-04-22) page 2, paragraph 4 -page 3, paragraph 1; example 1	1-3, 5, 6, 8, 9
	-/-	

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

### \* Special categories of cited documents :

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- "&" document member of the same patent family

Date of the actual completion of the international search

17 July 2000

Date of mailing of the international search report

07/08/2000

Name and mailing address of the ISA

European Patent Office, P.B. 5818 Patentlaan 2  
NL - 2280 HV Rijswijk  
Tel. (+31-70) 340-2040, Tx. 31 651 epo nl,  
Fax: (+31-70) 340-3016

Authorized officer

Johnson, K
